Improve packet validation for EVPN NLRIs and for ENCAP/VNC. Validate internal ip address fields against overall message length; impose stricter validation for VNC sub-tlvs in the rfapi code.

Greptile Summary

This PR hardens packet parsing for EVPN (Types 2, 3, and 4) and VNC/RFAPI by adding cross-validation between the internally-declared IP address length field and the overall NLRI wire-length, and by adding stricter sub-TLV length guards in the rfapi RIB path.

Key changes:

- **bgpd/bgp_evpn.c — Type-2:** A new `psize` vs. `ipaddr_len` consistency check is added *after* `ipaddr_len` has already been validated to be `0`, `32`, or `128`, so integer division is exact and no fringe values can slip through.

- **bgpd/bgp_evpn.c — Type-3** and **bgpd/bgp_evpn_mh.c — Type-4**: Similar cross-validation checks are added, but they are placed *before* the explicit bit-length guard against `IPV4_MAX_BITLEN / IPV6_MAX_BITLEN`. Because `psize` is independently constrained to two legal values before these checks run, any non-byte-aligned `ipaddr_len` that passes via truncating integer division (e.g., `33/8 == 4`) will still be rejected by the subsequent explicit bit-length comparison. There is no memory safety risk, but the ordering means the new guards are not independently sufficient on their own.
- **bgpd/rfapi/rfapi_rib.c**: Two new guards prevent processing a `BGP_VNC_SUBTLV_TYPE_RFPOPTION` sub-TLV whose `pEncap->length` is less than 3 (which would allow a zero-byte allocation and a potentially out-of-bounds `value[1]` read) or whose declared option length (`value[1]`) is zero. This closes a previously identified vulnerability where `XALLOC(..., 0)` could be called, the allocation would succeed, and a warning-and-shrink loop would produce a `hop` with a zeroed length.

Confidence Score: 4/5

- This PR is safe to merge — all new validation checks are defensive guards that reject malformed input and do not introduce new memory safety issues.
- The changes add strictly defensive input validation. The rfapi fix is clean and complete. For EVPN Types 3 and 4, the new size check uses integer division before `ipaddr_len` is validated against canonical values, meaning non-byte-aligned values can pass it — but they are caught by the subsequent explicit bit-length check, so no unsafe memory operation can occur. The Type-2 check is ordered correctly and is fully robust. Score docked one point because of the ordering inconsistency between Type-2 and Types 3/4, which leaves the new guards in Types 3/4 not independently sufficient.
- No files require special attention; the logic is correct and no regressions are expected.

Important Files Changed

Filename	Overview
<code>bgpd/bgp_evpn.c</code>	Adds cross-validation of <code>ipaddr_len</code> against <code>psize</code> for Type-2 (after prior <code>ipaddr_len</code> validation — robust) and Type-3 (before <code>ipaddr_len</code> validation against valid bit-lengths — relies on subsequent check to reject fringe values). No memory safety issues introduced.
<code>bgpd/bgp_evpn_mh.c</code>	Adds <code>psize / ipaddr_len</code> cross-validation for Type-4 routes. The outer <code>psize</code> check (lines 830–836) against the two legal sizes already constrains <code>psize</code> ; the new check further ensures the internal ip-len field is consistent with that size. Safe due to subsequent explicit bit-length check.
<code>bgpd/rfapi/rfapi_rib.c</code>	Adds two guards for <code>BGP_VNC_SUBTLV_TYPE_RFPOPTION</code> : rejects sub-TLVs shorter than 3 bytes (preventing out-of-bounds <code>value[1]</code> access and zero-byte allocations) and rejects a declared option length of zero.

Filename	Overview
	Allocation and memcpy are now always operating on at least 1 byte. Change is correct and complete.
